Abstract. It is important to be able to program GUI applications in a fast and easy manner. Current GUI tools for creating visually attractive applications offer limited functionality. In this paper we introduce a new, easy to use method to program GUI applications in a pure functional language such as Clean or Generic Haskell. The method we use is a refined version of the model-view paradigm.

The basic component in our approach is the Graphical Editor Component (GEC_τ) that can contain *any* value of *any* flat data type τ and that can be freely used to display and edit its value. GEC_τ s can depend on others, but also on themselves. They can even be mutually dependent. With these components we can construct a flexible, reusable and customizable editor. For the realization of the components we had to invent a new generic implementation technique for interactive applications.

1 Introduction

Making an attractive Graphical User Interface (GUI) for an application is not an easy task. One can of course use the GUI library offered by the operating system (Windows, Mac, Linux). These GUI libraries are powerful (they determine what is possible on a particular OS), but the offered level of abstraction is in general rather low. Therefore, most people will prefer to use a visual editor as offered by many commercial programming environments. Such tools are very user friendly at the expense of offering limited functionality. One still has to combine the graphical elements made with the visual editor with the program code for handling the actual GUI events. Inherently, graphical representations that depend on run-time data cannot be drawn in advance. Summarizing, a visual editor is a nice tool for certain simple GUI applications, but for more complicated ones one still has to struggle with low level programming code.

For dealing with more complicated applications in a simpler way, we want to define GUIs on a higher level of abstraction. Modern, pure functional programming languages enable the definition and construction of high abstraction levels. The Object I/O library [1] is probably the largest, GUI library available for pure functional languages. GUI applications can be defined in Object I/O in a platform independent way. The Object I/O library has been defined in Clean and is currently available for Windows and MacOSX. A subset has been ported to Linux [11]. Recently, Object I/O has been ported to Haskell as well by Peter Achten and Simon Peyton Jones [2]. This port was extended and applied

in a larger project by Krasimir Angelov [4]. Also recently, it has become possible to combine Haskell programs with Clean programs [12, 10]. Hence, in various ways Object I/O is nowadays available for a large community of pure functional programmers.

In Clean, impressive GUI applications have been made using Object I/O: e.g. the Clean IDE (including a text editor and a project manager), 2D-platform games, and the proof assistant Sparkle. The latter application in particular demonstrates the expressive power of Object I/O.

We have experienced that GUI elements such as dialogs, menus, and simple windows are relatively easy to define on a high level of abstraction. An application like the proof assistant Sparkle requires much more knowledge of the Object I/O primitives. In Sparkle [9], an action in one window (e.g. the completion of the proof of a theorem) has many consequences for the information displayed in the other windows (e.g. the list of completed theorems). Sparkle in this respect resembles the behavior of applications that are made with the well-known *model-view* paradigm [18]. The message passing primitives of Object I/O can handle such a complicated information flow. However, the learning curve to program such complicated mutual influences is rather steep.

Clearly, we need better tools to construct GUI applications on a high level of abstraction. However, we require that these tools are not as restrictive as standard GUI builders. Furthermore, we want to be able to create GUI applications in a versatile way. On the one hand it must be easy to combine standard components and on the other hand these components should be easily customized to adapt to our wishes.

In this paper we fulfill this need by introducing a new and very easy way for constructing GUI elements that respond to the change of other GUI elements. Proper customization requires a rigid separation of value versus visualization, and has led to a refined version of the model-view paradigm. The basic idea is the concept of a Graphical Editor Component (a GEC_τ) with which one can display and edit values of *any* flat¹ type τ . Any change in a value is directly passed to all other GEC_τ s that depend on the changed value. Using generic programming techniques, a GEC_τ for a certain concrete (user defined) type τ can be generated automatically. Apart from defining the data type and customization definitions almost no additional programming effort is needed. All low level communication that is required to accomplish the information flow between the graphical elements, is taken care of by the system. The proposed technique is *universal*, *customizable* and *compositional*. Moreover, it is a nice and novel application of generic programming [13].

In Sect. 2 we present the basic idea of a GEC_τ . Sect. 3 shows how these GEC_τ s can be combined to construct more complicated GUIs. In Sect. 4 we reveal how a GEC_τ is implemented using generic programming techniques. Sect. 5 explains how a GEC_τ can be customized to display its components in an alternative way. Thereafter, we will discuss related work. Finally, we draw conclusions and point out future work.

¹ A *flat* type is a type that does not contain any function types.

2 The concept of a Graphical Editor Component

We want to be able to make complicated GUI applications with minimal programming effort. The basic building block of our method is a customizable Graphical Editor Component (GEC_τ), which we can generate automatically for any flat type τ . More precisely, a GEC_τ is a generated function that contains a value of type τ and creates a visual component that:

1. can be used by a programmer to automatically display *any* value of type τ ;
2. can be used by the application user to view and edit a value of type τ ;
3. can be customized by a programmer such that its elements can be displayed in an alternative way;
4. can communicate any value change made by the user or by the program to any other component that depends on that change.

It is important to note that a GEC_τ is a very general component: in languages such as `Clean` and `Haskell`, every expression represents a value of a certain type. Since a GEC_τ can display any value of type τ , it can also be used to display any object (expression) of that type. Each GEC_τ is completely tailored to its type τ . It guarantees that each value edited is well-typed.

2.1 Generic programming and interactive functional programming

Before continuing, we have to make a few remarks for people unfamiliar with generic functions and functions that perform I/O in `Clean`.

Firstly, the type of a generic function shows that it is *generic* in \mathfrak{t} . This means that the function can be applied to a value of any concrete (predefined or user defined) type \mathfrak{t} . For more information on generic programming we refer to Sect. 4.1 and [13, 3, 8].

Secondly, `Object I/O` uses an explicit environment passing style [1] supported by the uniqueness type system of `Clean`. Consequently, any function that does something with I/O (like `mkGEC` in Sect. 2.2) is an explicit state transition function working on a program state (`PSt st`) returning at least a new program state. The uniqueness type system of `Clean` (see [5]) will ensure single threaded use of such a state. In the `Haskell` variant of `Object I/O`, a state monad is used instead. Uniqueness type attributes that actually appear in the type signatures are not shown in this paper, in order to simplify the presentation.

2.2 Creating GEC_τ s

In this section we explain in general terms what the generic function to create GEC_τ s, `mkGEC`, does. In the next section we will show how `mkGEC` can be used to connect different GEC_τ s.

In order to create a GEC_τ one only has to apply the generic function `mkGEC` which has the following type:

```

:: CallbackFunction t ps := t (PSt ps) ->2 PSt ps

generic mkGEC t :: [GECAttribute] t (CallbackFunction t ps) (PSt ps)
                -> (GEC t (PSt ps), PSt ps)

```

Hence, in order to call `mkGEC` the following arguments have to be provided:

- a `GECAttribute` list controlling behavioral aspects (`Editable` or `OutputOnly`) as well as visual aspects (such as window/dialog, relative/absolute position, etc.),
- an initial value of type `t`,
- a callback function defined by the programmer that will be called automatically each time the value of type `t` is edited by the user or by the program,
- the current unique state of the program.

The function `mkGEC` returns

- a record (`GEC`) containing methods that can be used to handle the newly created GEC_t component for type `t`, and
- the new unique program state (as usual for I/O handling functions in `Clean`).

```

:: GEC t pSt = { ...
                , gecGetValue :: pSt -> (t, pSt)
                , gecSetValue :: t pSt -> pSt
                }

```

The `GEC` record that is returned contains several other useful methods for a program that are not shown above. These are methods to open and close the created GEC_τ or to show or hide its appearance. For application programmers the methods `gecGetValue` and `gecSetValue` are the most interesting. The method `gecGetValue` can be used to obtain from the GEC_τ component the currently stored value of type `τ` . The method `gecSetValue` can be used to *set a new* value in the corresponding GEC_τ .

When the user of the application changes the content of a GEC_τ , the corresponding callback function will be automatically called with the new value. This callback function can be used to store new values in other GEC_τ s using the `gecSetValue` method of these GEC_τ s as will be demonstrated in Sect. 3.

The appearance of a standard GEC_τ is illustrated by the following example. Assume that the programmer has defined the type `Tree a` as shown below and consider the following application of `mkGEC`:

```

:: Tree a = Node (Tree a) a (Tree a) | Leaf

mkGEC my_GECAttribs (Node Leaf 1 Leaf) identity3 pSt

```

This defines a window containing the GEC_{TreeInt} displaying the indicated initial value (see Fig. 1). The application user can edit this initial value in any

² The `Clean` type `a b -> c` is equivalent to the Haskell type `a -> b -> c`.

³ In several examples `identity` will be used as a synonym for `const id`.

desired order thus producing new values of type `Tree Int`. Each time a new value is created, the call-back function `identity` is called automatically. In this example this has no effect (but see Sect. 3). The shape and lay-out of the tree being displayed adjusts itself automatically. Default values are made up by the editor when needed.

Fig. 1. The initial Graphical Editor Component for a tree of integers (Left) and a changed one (Right: with the pull-down menu the upper `Leaf` is changed into a `Node`).

Notice that a GEC_τ is strongly typed. Only well-typed values of type τ can be created with a GEC_τ . Therefore, with a $GEC_{TreeInt}$ the user can only create values of type `Tree Int`. If the user makes a mistake, for instance by typing an arbitrary string into the integer box, the previous displayed integer value is restored. Any created editor also includes many other goodies for free, such as: automatic scroll facilities, an automatic hint box showing the type of any displayed item, and the option to hide and show any part of a data structure. All of this is generated completely given a type τ .

3 Combining Graphical Editor Components

In this section we will give some small examples how GEC_τ -s can be combined. A simple combination scheme is the following. If one $GEC_\tau B$ depends on a change made in a $GEC_\sigma A$, then one can pass $GEC_\tau B$ to the callback function of A . Each time A is changed, its callback function is called automatically and as a reaction it can set a new value in B by applying a function of type $\sigma \rightarrow \tau$. Below, conform this scheme, two such GEC_τ -s are created in the function `apply2GECs` such that the call-back function of `GEC_A` employs `GEC_B`.

```

apply2GECs :: (a -> b) a (PSt ps) -> (PSt ps)
apply2GECs f va pst
  #4 (GEC_B, pst) = mkGEC my_GECAttribs1 (f va) identity pst
  # (GEC_A, pst) = mkGEC my_GECAttribs2 va (set GEC_B f) pst
  = pst

```

⁴ The `#`-notation of `Clean` has a special scope rule such that the same variable name can be used for subsequent non-recursive `#`-definitions.

```
set5 :: (GEC b (PSt ps)) (a -> b) a (PSt ps) -> (PSt ps)
set gec f nva pst = gec.gecSetValue (f nva) pst
```

With these definitions, `apply2GECs toBalancedTree [1,5,2,8,3,9] pst`, results in two GEC_{τ} s. One for a `[Int]`, and one for a `Tree Int`. Assuming that `toBalancedTree` is a function that transforms a list into a balanced tree, any change made by the user to the displayed list⁶ will automatically result into a corresponding re-balanced tree being displayed (see Fig. 2).

Fig. 2. A $GEC_{[Int]}$ window displaying an editable list (initially `[1,5,2,8,3,9]`) and an non-editable $GEC_{TreeInt}$ window showing the effect of applying the function `toBalancedTree` to that list.

Actually, the $GEC_{[Int]}$ is used by the application user to edit the list and the $GEC_{TreeInt}$ is used by the program to display the effect, controlled by the `GECAttribute OutputOnly`.

As this example demonstrates, combining GEC_{τ} s is very easy. One GEC_{τ} can have an effect on arbitrary many GEC_{τ} s including itself. Take for instance the function `selfGEC`.

```
selfGEC :: (a -> a) a (PSt ps) -> (PSt ps)
selfGEC f va pst = new_pst
where7
  (thisGEC, new_pst) = mkGEC my_GECAttribs (f va) (set thisGEC f) pst
```

Initially, this function displays the effect of applying a given function `f` to a given value `va` of type `a`. Any change a user makes using the editor automatically causes a re-evaluation of `f` to the new value thus created. Consequently, `f` has to be a function of type `a → a`. For example, one can use `selfGEC` to display and edit a balanced tree. Now, each time the tree is edited, it will re-balance *itself*. Notice that, due to the explicit environment passing style, it is trivial in `Clean` to connect a GEC_{τ} to itself. In `Haskell`'s monadic I/O one needs to tie the knot with `fixIO`.

⁵ This function `set` will also be used in other examples.

⁶ A `Clean` list is internally represented with the constructors `_Nil` and `_Cons`.

⁷ The `#`-notation can not be used here since the definition of `thisGEC` is recursive.

In a similar way one can define mutually dependent GEC_{τ} -s. Take the following definition of `mutual_GEC`.

```
mutual_GEC :: a (a -> b) (b -> a) (PSt ps) -> (PSt ps)
mutual_GEC va a2b b2a pst = pst2
where
  (GEC_B,pst1) = mkGEC my_GECAttribs (a2b va) (set GEC_A b2a) pst
  (GEC_A,pst2) = mkGEC (below my_GECAttribs) va (set GEC_B a2b) pst1
```

This function displays two GEC_{τ} -s. It is given an initial value `va` of type `a`, a function `a2b :: a -> b`, and a function `b2a :: b -> a`. The GEC A initially displays `va`, while GEC B initially displays `a2b va`. Each time one of the GEC_{τ} -s is changed, the other will be updated automatically. The order in which changes are made is irrelevant. For example, the application `mutual_GEC {euros = 3.5} toPounds toEuros` will result in an editor that calculates the exchange between pounds and euros (see Fig. 3) and vice versa.

```
exchangerate = 1.4

:: Pounds = {pounds :: Real}
:: Euros  = {euros  :: Real}

toPounds :: Euros -> Pounds
toPounds {euros} = {pounds = euros / exchangerate}

toEuros  :: Pounds -> Euros
toEuros  {pounds} = {euros = pounds * exchangerate}
```

Fig. 3. Two GEC_{τ} -s this time displayed in the same dialog, each displaying an editable record (Pounds and Euros). Any change in one of them updates the other.

The example of Fig. 3 may look a bit like a tiny spreadsheet, but it is essentially different since standard spreadsheets don't allow mutual dependencies between cells. Notice also the separation of concerns: the way GEC_{τ} -s are coupled is defined completely separate from the actual functionality.

4 Implementation Design of GEC_{τ} -s

It is of course not possible to describe all relevant implementation aspects in this paper. We restrict ourselves to the key aspects of the design.

4.1 Generic Functions

Recently, generic functions have been added to Clean [3]. A generic function is an ultimate reusable function that allows reflection on the structure of any data

in a type safe way. A generic function is actually a special kind of overloaded function. To define a generic function, instances have to be defined for a finite number of types, the *generic types*. The generic types have the property that any value of any type in the language can be represented by a specific combination of values of the generic types.

```

:: Unit      = Unit
:: Either a b = Left a | Right b
:: Pair a b   = Pair a b
:: TypeCons a = TypeCons InfoT a
:: DataCons a = DataCons InfoC a

```

The generic types consist of the basic types (`Bool`, `Int`, `Real`, `...`, which are used to represent themselves), `Unit` (to represent a zero arity data constructor), `Pair` (product type, used to combine arguments of data constructors), and `Either` (the sum type to indicate which data constructor of a certain type is used). Furthermore, there are two special additional types `TypeCons` and `DataCons`. They contain additional information (in `InfoT` and `InfoC`) about the name and arity of the original type and data constructors. This is useful for making generic functions that can parse or print. We will need them to display the values in our graphical editor.

With a collection of generic types, values of any user-defined type can be represented, e.g. `[1] :: [Int]` is represented by `TypeCons _List (Left (DataCons _Cons (Pair 1 (TypeCons _List Right (DataCons _Nil Unit))))))`, see also Fig. 4 on page 10.

Once defined by the programmer, a generic function can be applied to values of any concrete (user defined) type. The compiler will automatically add conversion functions (*bimaps*) that will transform the concrete type to the corresponding combination of generic types. Furthermore, the generic types returned by the generic function are converted back again to the actual type demanded.

In order to be able to deal with (mutual) recursive types, it is *vital* that these transformations are done in a lazy way (see [14] and [3]).

Generic functions are very useful for defining work of a general nature. Because generic functions can be specialized for any specific concrete type as well, they can also be customized easily. So far, the technique has been successfully used to define functions like equality, map, foldr, as well as for the construction of various parsers and pretty printers. Also, generic programming techniques play an important role in the implementation of automatic test systems [17]. The use of generic programming techniques for the creation of GUI applications has to our knowledge never been done before.

4.2 Creating a GEC_τ with generic functions

A GEC_τ component basically is an interactive editor for data of type τ , which can be edited in any order. A special property of such an editor is that all data elements have to be visualized and still have to be modifiable *as well*.

One might be tempted by the idea to design some suitable universal type, make a visual editor with which values of this type can be modified, and convert the changed value back to the actual type. However, it is a fundamental property of the language that (without some kind of reflection) there cannot exist a single universal type with which values of any type can be represented.

The types used by the generic function definitions approximate that universal type idea. However, they do not constitute a single type but a *family of types*. Each concrete user defined type is represented by a different combination of members of this generic type family. Such a particular representation by itself has a type that depends on the combination of values of the generic types that is used.

For our kind of interactive programs generic functions cannot be used in the standard way (in which a user type is converted lazily to the generic representation after which the generic function is applied and the result is converted back again). We need a variant in which the generic representation is not discarded but persists somehow, such that interactions (and corresponding conversions to the user types) can take place.

Consequently, we have to create a family of objects of different types to accommodate the generic representation. One solution might be to create a family of functional heaps (like `MVars`) each with a different type. This family of heaps should then be used to create the required interactive functionality. It is however much easier to use *receiver objects*, a facility of `Object I/O`.

Using existentially quantified types these receiver objects (or, in short, *receivers*) can have an internal state in the same way as functional heaps do. They are more flexible because one can attach an arbitrary number of arbitrary methods to them, based on the message passing primitives in `Object I/O`. In this way, receivers enable an object-oriented style of programming. The specialized receivers that we use to ‘manage’ τ values will be identified by values of abstract type `(GECId τ)`. These values are generated with the function `openGECId`. Of course, `Clean`’s uniqueness typing guarantees the side-effect free single threaded use of these receiver objects.

Using receivers, we have created a family of objects and corresponding keys of different types. For every member of the generic type family that we need in a specific representation, a separate receiver is created. In this way we have created a collection of objects hidden in the heap that refer to each other using identification keys. The topology of the receiver objects is similar to the generic representation.

In Fig. 4 we show the objects that are created to represent the value [1] generically. Notice the similarity between the generic representation and the topology of the receiver objects created. For this particular value, 11 receiver objects are initially created. The figure reveals that, compared to the generic representation, two additional (inactive) receivers (indicated by dark grey boxes, one marked `Nil ::` and one marked `Cons ::`) have been created. The reason is that in order to allow a user to change a constructor to another one, the infrastructure to handle that other constructor must already be available.

Fig. 4. The representation of [1] using generic types (Left), and the topology of the created receiver objects (see page 9) representing the same expression (Right).

The methods of the receiver objects set up the *communication infrastructure*. Actually, the methods in the GEC_τ -record are carried applications of the receiver methods with the corresponding identification key. For instance, an object can ask another object to return its current value, it can set a new value in another object, it can ask an object to hide or display its graphical representation. When the application user plays with the editor, the receiver objects will tell each other what to do. For instance, when a leaf value in the tree of receivers is changed, all spine receiver objects that depend on it will be informed.

In general, a lot of communication takes place when the application user operates the editor. The required underlying communication infrastructure is far from trivial, but we only have to define it once. Each receiver object of a certain (generic) type furthermore requires a view to display and edit a value of that type. How this view can be adapted, is explained in Sect. 5.

Once the editor is created for a certain type and the corresponding views have been created, the application user can use the views to edit the value. For the implementation this means that receivers have to be created dynamically as well. For instance, if the application user makes a larger structure (e.g. [1,2]) out of a smaller one (e.g. [1]), we have to increase the number of receivers accordingly. It is possible that a receiver is not needed anymore because the user has chosen some other value. Receivers are only deleted when the whole editor is closed. Until then we mark unused receivers as inactive but remember their values. We simply close the views of these inactive receivers and reopen them when the user regrets his decision. In this way the application user can quickly switch from one value to another and backwards without being forced to retype information.

When a user switches from one data constructor to another, we have to create default values. For instance, if a Nil is changed into a Cons using an editor for a list of integers, we will generate `Cons 0 Nil` as default. We use a generic function to make up such a default value. A programmer can easily change this by specializing this generic default function for a particular type.

5 Customizing Graphical Editor Components

5.1 The Counter example

No paper about GUIs is complete without the counter example. To make such a counter we need an integer value and an up-down button. The counter has to be increased or decreased each time the corresponding button is pressed. Notice that our editors only react to changes made in the displayed data structure. Consequently, if the application user chooses `Up` two times in a row, the second `Up` will only be noticed if its value was not `Up` before. Therefore, we need a three state button with a neutral position (`Neutral`) that can be changed to either `Up` or `Down`. After being pressed it has to be reset to the neutral position again. The counter can be created automatically by applying `selfGEC updCtr (0,Neutral)`, using the concise and simple definitions in Fig. 5.

```
:: UpDown      = Up | Down | Neutral
:: Counter    ::= (Int,UpDown)

updCtr :: Counter -> Counter
updCtr (n,Up)   = (n+1,Neutral)
updCtr (n,Down) = (n-1,Neutral)
updCtr any     = any
```

Fig. 5. Two GEC_{Counter} s. The standard one (on Top) and a customized one.

The definition of the counter, the model, is very intuitive and straightforward. The generated GEC_{Counter} works as intended, and we get it for free. However, its view is a counterexample of a good-looking counter (bottom window in Fig. 5). In this case it would be nicer to hide the tuple data constructor editor, and instead of displaying the integer box above the button, it is nicer to have them next to each other. And would it not be nice to display  instead of `Neutral` that we generate as default editor for values of the type `UpDown`?

5.2 Full Customization

One of the goals in this project was to obtain fully customizable GUI editors. Here, we explain how this can be done.

Each receiver object that is generically created by the instances of `mkGEC` requires a graphical editor definition that will tell how a value of that type can

be displayed and edited. This is done by a set of ‘mirror’ functions that take an additional parameter:

```
generic mkGEC t :: [GECAttribute] t (CallBackFunction t ps) (PSt ps)
                                     -> (GEC t (PSt ps),PSt ps)
mkGEC{|Unit|} ... = unitGEC   unitGUI   ...
mkGEC{|Pair|} ... = pairGEC   pairGUI   ...
mkGEC{|Either|} ... = eitherGEC eitherGUI ...
mkGEC{|Int|} ... = basicGEC   intGUI    ...
      // other basic types proceed analogously
```

The additional parameter (e.g. `unitGUI`) defines the view. It is a function of type `env → (GECGUI t env,env)`: an environment based function in order to allow it to allocate the necessary resources. Hence, the view of a GEC_t is defined by a $GECGUI_t$. A $GECGUI_t$ on an environment `env` yields a record with the following methods:

1. `guiLocs` reserves GUI screen space for the subcomponents of `t`. It is a function that returns a list of GUI locations⁸, given its own location. For this reason it has type `Location → [Location]`.
2. `guiOpen` creates the view and the reserved GUI screen estate, given its own location. Hence, it must be an action. It has type `Location → env → env`.
3. `guiUpdate` defines how a new value set from the outside⁹ has to be displayed. It has the obvious type `t → env → env`.
4. `guiClose` closes the view (usually a trivial Object I/O close action, which is the inverse operation of 2 above). It has the action type `env → env`.

As can be seen from the ‘mirror’ functions above, we have defined such a default editor for all generic types. For any (user defined) type, an editor is constructed by combining these generic editors. The specialization mechanism of `Clean` can be used to change any part of a GEC_t since specialized definition for a certain type will overrule the default editor for that type. Therefore, to create a good-looking counter one only has to redefine the editor for `(,)` and `UpDown`. $GECGUI_{UpDown}$ is created by:

```
mkGEC{|UpDown|} ... pSt
  # (tGEC,pSt) = openGECId pSt           // identification for the GEC receiver
  = basicGEC (updownGUI (setVECvalue tGEC)) ... pSt
```

To show the effect of the customized representation, we construct a slightly more complicated example. Below, in the record structure `DoubleCounter` we store two counters and an integer value, which will always display the sum of the two counters. Notice that the programmer can specify the wanted behavior just by applying `updCntr` on each of the counters. The sum is calculated by taking

⁸ The number of elements is actually dependent on the kind: zero for \star , one for $\star \rightarrow \star$, two for $\star \rightarrow \star \rightarrow \star$ etc.

⁹ Note that the other direction is simply a parameter of the editor component.

the sum of the resulting counter values. One obtains a very clear specification without any worry about the graphical representation or edit functionality. All one has to do is to apply `selfGEC updDoubleCntr` to the initial value `{counter1 = (0,Neutral), counter2 = (0,Neutral), sum = 0}`.

```

:: DoubleCounter = { counter1 :: Counter
                    , counter2 :: Counter
                    , sum      :: Int
                    }

updDoubleCntr :: DoubleCounter -> DoubleCounter
updDoubleCntr cntr
  = { counter1 = newcounter1
    , counter2 = newcounter2
    , sum      = fst newcounter1 + fst newcounter2
    }
where newcounter1 = updCntr cntr.counter1
      newcounter2 = updCntr cntr.counter2

```

Fig. 6. An editor with two counters and a resulting sum.

For large data structures it may be infeasible to display the complete data structure. Customization can be used to define a GEC_{τ} that creates a view on a finite subset of such a large data structure with buttons to browse through the rest of the data structure. This same technique can also be used to create GEC_{τ} s for lazy infinite data structures. For these infinite data structures customization is a must since clearly they can never be fully displayed.

6 Related Work

The system described in this paper is a refined version of the well-known *model-view* paradigm [18], introduced by Trygve Reenskaug in the language *Smalltalk* (then named as the *model-view-controller* paradigm).

In our approach the data type plays the *model* role, and the *views* are derived automatically from the generic decomposition of values of that type. The *controller* role is dealt with by both the automatically derived communication infrastructure and the views (as they need to handle user actions). Because views are derived automatically, a programmer in our system does not need to explicitly ‘register’ nor program views. Views can be customized via overruling instance declarations of arbitrary types.

A distinguishing feature of our approach is the distributed nature of both the model and the views. The model is distributed using the generic decomposition of the model value. The subvalues are stored in the receivers. This implies that it should be relatively easy to distribute this framework over a collection of

distributed interactive processes. The view is distributed as well, as each view of a generic component is responsible for showing that particular generic instance only. Its further responsibility is to define GUI space for the subcomponents.

Frameworks for the model-view paradigm in a functional language use a similar value-based approach as we do [7], or an event-based version [15]. In both cases, the programmer needs to explicitly handle view registration and manipulation. In our framework, the information-flow follows the structure that is derived by the generic decomposition of the model value. This suggests that we could have used a stream-based solution such as FUDGETS [6]. However, stream based approaches are known to impose a much too rigid coupling between the stream based communication and the GUI structure resulting in a severe loss of flexibility and maintainability. For this reason, we have chosen to use a callback mechanism as the interface of our GEC_τ components.

The Vital project [16] has similar goals as our project. Vital is an interactive graphical environment for direct manipulation of Haskell-like scripts. Shared goals are: direct manipulation of functional expressions (Haskell expressions vs. flat values), manipulation of custom types, views that depend on the data type (*data type styles*), *guarded* data types (we use `selfGEC`), and the ability to work with infinite data structures. Differences are that our system is completely implemented in Clean, while the Vital system has been implemented in Java. This implies that our system can handle, by construction, all flat Clean values, and all values are obviously well-typed. In addition, the purpose of a GEC_τ is to edit values of type τ , while the purpose of a Vital session is to edit Haskell scripts.

7 Conclusions and Future Work

Graphical Editor Components are built on top of the Object I/O GUI library. The Object I/O library offers a lot of functionality (e.g. one can define menus, draw objects, make timers, etcetera) and it is also very flexible, but at the expense of a steep learning curve. Graphical Editor Components offer a more limited functionality: a customizable view and editor for any type. The customization abilities make it possible to incorporate the functionality of Object I/O. It does not exclude Object I/O; it is fully integrated with it. You can still use windows, dialogs, menus, timers, and so on. The abstraction layer offered by the Graphical Editor Components is much higher and the learning curve is short and flat. The most important advantages are:

- for any value of any flat type one gets an editor for free;
- the editor can be used to give type safe input to the application;
- any output or intermediate result can be displayed;
- an editor can be customized by redefining the components one wants to display in another way;
- editors can be easily combined including mutually dependent editors;
- visualization is separated from the value infrastructure and it is completely customizable.

The presented method offers a good separation of concerns. The specification of the wanted functionality of a component is completely separated from the specification of its graphical representation. One even obtains a default graphical representation for free. Also one can abstract from the way components are connected. As a result, complicated interactive applications can be created without a lot of understanding of graphical I/O handling.

Editors can be used for programming GUI objects, from simple dialogs to complicated spreadsheets. They can also be used for tracing and debugging.

The automatic generation of components was only possible thanks to the generic programming facilities of Clean. The interactive nature of the components caused some interesting implementation problems. We had to store the generic representation in special objects (Object I/O receivers). We also hit on a disturbing limitation of the current implementation in Clean: one cannot overload generic functions in their generic type. For this reason we introduced the ‘mirror’ functions in Sect. 5. We intend to solve this.

We plan to extend the system with support for non-flat types. This will require the ability to deal with function types. An interesting direction of research seems to be to use the Esther shell of the experimental operating system Famke, which deals with creating and composing functions in an interactive and dynamically typed way. This shell is written in Clean as well [19].

Furthermore, we will investigate the expressive power of our graphical editor components. We will do this by constructing larger applications. In this way we hope to find out what goodies are missing, what other variants might be needed, and what kind of additional support (e.g. editor combinators) is wanted.
